NAME
>   curl_global_init_mem - Global libcurl initialisation with memory callbacks

SYNOPSIS
>   **#include <curl/curl.h>**
>   **CURLcode curl_global_init_mem(long flags,**
>   **curl_malloc_callback m,**
>   **curl_free_callback f,**
>   **curl_realloc_callback r,**
>   **curl_strdup_callback s,**
>   **curl_calloc_callback c);**

DESCRIPTION
>   This function works exactly as *curl_global_init(3)* with one addition: it allows the application to set call-
>   backs to replace the otherwise used internal memory functions.
>
>   When you use this function, all callback arguments must be set to valid function pointers. **If you are using**
>   **libcurl from multiple threads or with the threaded resolver (the default in Windows) the callback**
>   **replacement functions must be thread safe.**
>
>   The prototypes for the given callbacks should match these:
>
>   void *malloc_callback(size_t size);
>   To replace malloc()
>
>   void free_callback(void *ptr);
>   To replace free()
>
>   void *realloc_callback(void *ptr, size_t size);
>   To replace realloc()
>
>   char *strdup_callback(const char *str);
>   To replace strdup()
>
>   void *calloc_callback(size_t nmemb, size_t size);
>   To replace calloc()
>   This function is otherwise the same as *curl_global_init(3)*, please refer to that man page for documentation.

CAUTION
>   Manipulating these gives considerable powers to the application to severely screw things up for libcurl.
>   Take care!
